EFFECTS OF PRESSURE ON ORGANIC REACTIONS III

The Base-Catalyzed Reduction
of Diisobutylketone

BY TAKASHI MORIYOSHI AND MASAHIRO HIRATA

The rate of the base-catalyzed reduction of diisobutylketone to carbinol in *n*-butanol solution has been measured in the range 96~112°C at pressures up to 1,450 bar. The reaction is kinetically of second order in both ketone and base, and is accelerated by pressure. The energies of activation at 1 bar and 964 bar are 26.4 kcal/mole and 26.6 kcal/mole, respectively, and the volume of activation is about $-13\text{ cm}^3/\text{mole}$ at 99.00~100.27°C. These results show favorably that the slow step is a bimolecular reaction, probably the hydrogen abstraction, between two ketone-alkoxide adducts formed in rapidly established initial equilibrium. In addition, it may be deduced that the acceleration of the reaction under pressure arises predominantly from the enhanced addition of alkoxide anion to ketone.

Introduction

The reduction of ketones by primary alcohols in the presence of alkaline has been well-known¹⁾. Although it may appear that the reaction is of Meerwein-Ponndorf-Verley type²⁾, represented as $\text{R}'\text{COR}'' + \text{RCH}_2\text{OH} \rightleftharpoons \text{R}'\text{CH}(\text{OH})\text{R}'' + \text{RCHO}$, the mechanism has not been established.

In the course of the investigation related with the self-condensation of ketone³⁾, we attempted to subject diisobutylketone to the action of sodium butoxide in *n*-butanol under pressure. The main product was the corresponding carbinol, and the other condensation products from ketone were not isolated.

Then, in order to make some mechanistic explanations about the reaction, a kinetic study has been made of the reduction of diisobutylketone under such conditions as in this paper.

Experimentals

Materials

Diisobutylketone was first distilled under reduced pressure. The middle fraction was dried over

night by standing over anhydrous potassium carbonate and then fractionally distilled twice, bp. 70.0~70.4°C/20 mm. *n*-Butanol was refluxed over freshly burned lime for 3 hours and distilled. The alcohol obtained was subsequently dried with anhydrous potassium carbonate and finally fractionally distilled, bp. 116.5~116.8°C. The sodium butoxide solution used as catalyst was prepared by dissolving metallic sodium in pure *n*-butanol under reflux in the stream of dry nitrogen to avoid moisture. The other chemicals used were of reagent grade and were purified by conventional means when necessary.

Analytical method

The rate of reaction was followed by determining the concentration of unchanged diisobutylketone by the gas chromatographic technique. The estimation of its amount from chromatogram was made by application of the internal standardization method with *iso*-amyl alcohol as a standard substance. The analysis was performed with a Shimadzu gas chromatograph model GC-1C, fitted with 7.5m of Ucone 500 column, at 150°C with 16.5 ml/sec, the flow rate of helium carrier gas. Since a linear relationship was satisfactorily found between the weight ratio of diisobutylketone to *iso*-amyl alcohol and the ratio of their peak heights rather than the peak areas, the calibration factor obtained from this relation was used to determine the amount of reactant from the chromatogram of the reaction mixture. Analytical error in this method was within ± 1 per cent.

Kinetic measurements

The reaction mixtures were prepared by the weight method using diisobutylketone, sodium butoxide solution and *n*-butanol as solvent, and the concentrations were expressed in terms of their molalities. The initial concentration of diisobutylketone was about 4.6 mole/kg-solvent in all runs. The concentration of butoxide in the mixture was determined by titration with the standard 0.18 *n*-hydrochloric acid in 50 per cent aqueous methanol solution.

The rates at ordinary pressure and high pressures were measured by using the apparatus and the technique similar to that described in the previous paper⁴⁾. The reaction vessel was placed in an oil-bath controlled within $\pm 0.05^\circ\text{C}$. Pressure was measured with a calibrated Bourdon gauge.

After the desired time, the sample removed from the vessel was cooled and pipetted into the weighed amount of *iso*-amyl alcohol, whose peak gave approximately the same height as that of the reactant in the chromatogram, and then the total mixture was finally weighed. Subsequently, the solution was neutralized with ethanolic hydrochloric acid solution and the supernatant solution was chromatographed.

Analysis of products

A large amount (ca. 200 ml) of the reaction mixture, containing nearly the same contents as in kinetic runs, was heated for 41 hours at 105°C for the separation of products. After the neutralization with hydrochloric acid, the unchanged reactant and the products were extracted with ether from the resulting solution. The extract was dried with anhydrous potassium carbonate, filtered and ether was removed by evaporation. The residue was distilled under reduced pressure in the stream of dry nitrogen, and two fractions were isolated. The first fraction as the main product was colorless oil, bp.

4) T. Moriyoshi and K. Tamura, *This Journal*, **40**, 48 (1970)

62.4~63.4°C/5.5 mm, d^{20}_D 0.8092, n^{25}_D 1.4209, and gave an infra-red spectrum containing a strong absorption band of OH stretching near 3,470 cm^{-1} , as shown in Fig. 1.

Fig. 1 Infra-red spectra

- a: diisobutylketone
- b: main product
- c: by-product

Anal. Found: C, 74.64; H, 13.56. Calc. for $\text{C}_9\text{H}_{20}\text{O}$: C, 74.93; H, 13.97.

3,5-Dinitrobenzoate derivative of this substance was prepared by the usual method and was recrystallized several times from methanol and ligroin, mp. 87.0~87.8°C.

Anal. Found: C, 56.87; H, 6.69; N, 8.04. Calc. for $\text{C}_{16}\text{H}_{22}\text{O}_6\text{N}_2$: C, 56.80; H, 6.55; N, 8.28.

From these evidences, this product was identified as diisobutylcarbinol.

The second fraction obtained in poor yield, no more than about 3 per cent to carbinol, was lightly yellowish oil, bp. 92.8~94.0°C/0.36 mm, n^{25}_D 1.4677, and exhibited a strong band due to C=O stretching at 1690 cm^{-1} in the spectrum.

Anal. Found: C, 80.26; H, 11.88. Calc. for $\text{C}_{11}\text{H}_{20}\text{O}$: C, 79.94; H, 11.18.

These results suggest that the by-product will be dehydrated trimer made from the aldol condensation of *n*-butylaldehyde formed by oxidation of solvent, but it is doubtful because the characteristic band of C=C stretching cannot be found in the spectrum.

Results

First, in order to determine an appropriate rate equation applicable to the present results, various equations were examined. Consequently, it was confirmed that the second order rate equation,

$$\frac{1}{C} - \frac{1}{C_0} = k_a t,$$

where C_0 is the initial concentration of ketone and C the concentration of that at any time t , was obeyed preferably at constant base concentrations over the range of measured conversion, usually up to about 30 per cent of complete reaction.

Some kinetic plots are illustrated in Figs. 2 and 3, and the apparent second order rate constants

k_a were obtained from their slopes. All the results are summarized in Table 1. The mean error in k_a was about within ± 2 per cent.

The dependence of the base concentration on the rate at 1 bar is shown graphically in Fig. 4, and a straight line with slope 2.0 is drawn through the points, except at the lowest concentration of base,

Fig. 4 Plot of $\log k_a$ vs $\log [C_B]$ at 99.45°C and 1 bar

○: 1 bar ●: 964 bar

to show the validity of the relation :

$$k_a = 1.65 \times 10^{-7} [C_B]^{2.0},$$

where $[C_B]$ denotes the concentration of base. The fourth order kinetics in the same manner, that is, second order in both aldehyde and alkaline, had been observed in some cases of Cannizzaro reaction⁵⁾.

The Arrhenius plots of the second order constants k_a at 1 bar and 964 bar are given in Fig. 5, in which from the slopes of the straight lines the energies of activation are calculated to be 26.4 kcal/mole and 26.6 kcal/mole, respectively.

The rate constants as a function of pressure at two temperatures are shown in Fig. 6. The volume of activation ΔV^* estimated graphically using the equation,

$$\left(\frac{\partial \ln k_a}{\partial P} \right)_T = - \frac{\Delta V^*}{RT},$$

is $-12.9 \text{ cm}^3/\text{mole}$ at 99.00°C and $-12.6 \text{ cm}^3/\text{mole}$ at 100.27°C.

Discussion

The base-catalyzed reduction of diisobutylketone to corresponding carbinol is found to be kinetically of second order in ketone and also of second order in base from the observed results, and then the reaction sequence may be given as follows:

In the above mechanism, if the addition of butoxide anion (B^-) to ketone (K) to form a ketone-alkoxide adduct (A^-) in the first step (i) is rapid and reversible, and also if the second step (ii) is the rate determining one so that both the steps (iii) and (iv) are fast compared with the step (ii) and play no part in the kinetics, then the rate is given by

$$\text{rate} = k_2 \left\{ \frac{k_1 [\text{K}] [\text{B}^-]}{k_{-1} + 2k_2 [\text{A}^-]} \right\}^2, \quad (1)$$

where k 's are the rate constants and the brackets denote the concentration terms.

In the limiting case where $k_{-1} \gg 2k_2 [\text{A}^-]$, the equation reduces to

$$\text{rate} = k_2 K_1^2 [\text{K}]^2 [\text{B}^-]^2, \quad (2)$$

where K_1 is the equilibrium constant for the first step (i), which is consistent with the present kinetic results, that is, the reduction is of second order in both ketone and base as shown in Fig. 4. Thus, the apparent second order rate constant k_a observed experimentally is given by

$$k_a = k_2 K_1^2 [\text{B}^-]^2, \quad (3)$$

Since the pressure dependence on the concentration term, which is given in the molality scale, could be eliminated, the effect of pressure on the rate constant may be expressed by

$$\left(\frac{\partial \ln k_a}{\partial P} \right)_T = - \frac{(2\Delta V_1 + \Delta V_2^*)}{RT}, \quad (4)$$

where ΔV_1 represents the volume change of the first step (i) and ΔV_2^* the volume of activation for the second step (ii). Hence, the actually observed value of ΔV^* may be given as a composite quantity from the following terms

$$\Delta V^* = 2\Delta V_1 + \Delta V_2^* \quad (5)$$

The first equilibrium step involves no change in ionic charge and consequently no large change in the electrostriction of solvent, but a new covalent bond between ketone and butoxide anion is formed so that obviously the over-all change in volume ΔV_1 should be slightly negative. The second step may be assumed to be the bimolecular abstraction of hydrogen between two ketone-alkoxide adducts. The volume of activation in this step reflects the contraction due to the formation of a partial valence bond ($\text{O}\cdots\text{H}$) outweighing the stretching of C-H bond and further the expansion caused by the dispersal of ionic charge.

The observed volume of activation for the reduction is $-13 \text{ cm}^3/\text{mole}$ as a whole, and there is no way of measuring ΔV_1 and ΔV_2^* directly. However, one can approach to the estimation of these values by considering other analogous reactions. If the change of volume accompanying a reaction of the same type, $\text{A} + \text{B}^- \rightleftharpoons \text{AB}^-$, as the first step would be roughly taken as being comparable to $-5 \text{ cm}^3/\text{mole}$ for the reaction, $\text{I}_2 + \text{I}^- \rightleftharpoons \text{I}_3^-$ ⁶⁾, then it follows from the equation (5) that $\Delta V_2^* \simeq -3 \text{ cm}^3/\text{mole}$.

A possible transition state from the proposed mechanism may be presumably represented as follows:

6) A. H. Ewald and S. D. Hamann, *Australian J. Chem.*, **9**, 54 (1956)

In view of the reaction type, the hydrogen abstraction by adduct anion is rather similar to exchange reactions, in which a new bond is formed and another is broken simultaneously as in the ionic displacement reactions. ΔV^* for the process of this kind has been observed to range from -5 to -10 cm³/mole⁷⁾ on the average. Also, the chain transfer reaction for the analogous reactions, involving only the structural contribution except for that of steric hindrance, has about -11 cm³/mole⁸⁾ for ΔV^* . In comparison with these results, the value of ΔV_2^* estimated above is apparently large enough.

As shown above, the transition state formed from two bulky anions appears to make a ring structure linked loosely, and there is some dispersal of ionic charge in the reaction sites, which should lead to solvent relaxation and result in the increase in volume, possibly accompanied by some steric exhaustion of solvent from the partly formed ring structure. Consequently, it follows from these considerations that the volume lost in this activation process should be less than expected by analogy with the exchange and the chain transfer reactions, and that the observed acceleration of the reaction at high pressures is probably caused by a shift of the preliminary equilibrium in favor of the adduct form.

The energies of activation evaluated at two pressures are larger than that for the self-condensation of ketone⁹⁾ by a factor of about 2, and this suggests the reaction will be energetically hard to occur. In addition, the entropies of activation at 1 bar and 964 bar, which are calculated from the rate constant divided by the second power of the concentration of base, are -21.2 cal/deg·mole and -20.0 cal/deg·mole, respectively. There is no appreciable change with pressure in these activation parameters.

The volume of activation can be also divided thermodynamically into two terms,

$$\begin{aligned}\Delta V^* &= \left(\frac{\partial \Delta G^*}{\partial P} \right)_T \\ &= \left(\frac{\partial \Delta H^*}{\partial P} \right)_T - T \left(\frac{\partial \Delta S^*}{\partial P} \right)_T.\end{aligned}$$

Calculating from the differences of two activation parameters between 1 bar and 964 bar according to the above equation, the value of ΔV^* is -10.7 cm³/mole at 99.00°C and -10.8 cm³/mole at 100.27°C, in fairly good agreement with that from the pressure dependence of the reaction rate.

Hamann, *Trans. Faraday Soc.*, **50**, 1188 (1954); J. Koskikallio and E. Whalley, *Can. J. Chem.*, **37**, 788 (1959); K. R. Brower, *J. Am. Chem. Soc.*, **85**, 1401 (1963); K. R. Brower and J. S. Chen, *ibid.*, **87**, 3396 (1965)

8) C. Walling and J. Pellon, *J. Am. Chem. Soc.*, **79**, 4776 (1957)

The present argument for the mechanism of the studied reduction seems to be still unsound and may involve somewhat illogical reasoning, because there is no doubt that in such a non-aqueous concentrated solution of base various species will exist and their functions as catalyst are complex. Therefore, more exact description about this will be possible from further experimental results.

The authors would like to express their thanks to Professor J. Osugi of Kyoto University for his advice and encouragement.
